

Chapter 2

Looking Closer at JavaFX Programming

In This Chapter

- ▶ Importing the classes you need to create a JavaFX program
 - ▶ Creating a class that extends the JavaFX `Application` class
 - ▶ Using classes such as `Button`, `BorderPane`, and `Scene` to create a user interface
 - ▶ Creating an event handler that will be called when the user clicks a button
 - ▶ Examining an enhanced version of the Click Me program
-

In Chapter 1, I introduce you to a simple JavaFX program called the Click Me program and briefly describe how that program works. In this chapter, I put this program under the microscope and examine it in close detail. By the time you finish this chapter, you'll understand how every line of the Click Me program works and why it's required. Then, you'll be ready to start figuring out more nuanced techniques of JavaFX programming.

Looking Again at the Click Me Program

Figure 2-1 shows the Click Me program in action. As you can see, this program displays a simple button that contains the words `Click me please!`. What the figure does not show is that when the user clicks the button, the text on the button becomes `I've Been Clicked!`.

Figure 2-1:
The Click
Me program
in action.

Although this program is simple, it demonstrates most of the essential techniques you need to master to figure out how to write JavaFX programs:

- ✔ It displays a user interface that includes a standard type of user interface control — in this case, a button.
- ✔ It responds to the user's input, generated when the user clicks the button.
- ✔ It updates the display to confirm the user's action.

Many JavaFX programs are variations of this simple theme: Create a user interface, respond to the user's input, and then update the display to reflect the user's input. The user interface displayed by a more realistic JavaFX program will undoubtedly display more than just a single button. The processing performed in response to user input will likely include additional steps, such as looking up information in a database or performing calculations. And the display will undoubtedly be updated in more complicated ways than simply changing the text displayed on a button. But variations on these basic elements are found in most real-world JavaFX programs.

Listing 2-1 shows the actual JavaFX code for the Click Me program. In the remaining sections of this chapter, I explain every line of this program in detail.

Listing 2-1: The Click Me Program

```
import javafx.application.*;
import javafx.stage.*;
import javafx.scene.*;
import javafx.scene.layout.*;
import javafx.scene.control.*;

public class ClickMe extends Application
{
    public static void main(String[] args)
    {
        launch(args);
    }

    Button btn;

    @Override public void start(Stage primaryStage)
    {
        // Create the button
        btn = new Button();
        btn.setText("Click me please!");
        btn.setOnAction(e -> buttonClick());

        // Add the button to a layout pane
        BorderPane pane = new BorderPane();
        pane.setCenter(btn);

        // Add the layout pane to a scene
        Scene scene = new Scene(pane, 300, 250);

        // Finalize and show the stage
        primaryStage.setScene(scene);
        primaryStage.setTitle("The Click Me App");
        primaryStage.show();
    }

    public void buttonClick()
    {
        if (btn.getText() == "Click me please!")
        {
            btn.setText("You clicked me!");
        }
        else
        {
            btn.setText("Click me please!");
        }
    }
}
```

Importing JavaFX Packages

Like any Java program, JavaFX programs begin with a series of `import` statements that reference the various JavaFX packages that the program will use. The Click Me program includes the following five `import` statements:

```
import javafx.application.*;
import javafx.stage.*;
import javafx.scene.*;
import javafx.scene.layout.*;
import javafx.scene.control.*;
```

As you can see, all the JavaFX packages begin with `javafx`. The Click Me program uses classes from five distinct JavaFX packages:

- ✓ **`javafx.application`:** This package defines the core class on which all JavaFX applications depend: `Application`. You read more about the `Application` class in the section “Extending the Application Class” later in this chapter.
- ✓ **`javafx.stage`:** The most important class in this package is `Stage` class, which defines the top-level container for all user interface objects. `Stage` is a JavaFX application’s highest-level window, within which all the application’s user-interface elements are displayed.
- ✓ **`javafx.scene`:** The most important class in this package is the `Scene` class, which is a container that holds all the user interface elements displayed by the program.
- ✓ **`javafx.scene.layout`:** This package defines a special type of user-interface element called a *layout manager*. The job of a layout manager is to determine the position of each control displayed in the user interface.
- ✓ **`javafx.scene.control`:** This package contains the classes that define individual user interface controls such as buttons, text boxes, and labels.

The Click Me program uses just one class from this package: `Button`, which represents a button that the user can click.

Extending the Application Class

A JavaFX application is a Java class that extends the `javafx.application.Application` class. Thus, the declaration for the Click Me application’s main class is this:

```
public class ClickMe extends Application
```

Here, the Click Me application is defined by a class named `ClickMe`, which extends the `Application` class.

Because the entire `javafx.application` package is imported in line 1 of the Click Me program, the `Application` class does not have to be fully qualified. If you omit the import statement for the `javafx.application` package, the `ClickMe` class declaration would have to look like this:

```
public class ClickMe
    extends javafx.application.Application
```

The `Application` class is responsible for managing what is called the *life-cycle* of a JavaFX application. The lifecycle consists of the following steps:

1. Create an instance of the `Application` class.
2. Call the `init` method.

The default implementation of the `init` method does nothing, but you can override the `init` method to provide any processing you want to be performed before the application's user interface displays.

3. Call the `start` method.

The `start` method is an abstract method, which means that there is no default implementation provided as a part of the `Application` class. Therefore, you must provide your own version of the `start` method. The `start` method is responsible for building and displaying the user interface. (For more information, see the section “Overriding the `start` Method” later in this chapter.)

4. Wait for the application to end, which typically happens when the user signals the end of the program by closing the main application window or choosing the program's exit command.

During this time, the application isn't really idle. Instead, it's busy performing actions in response to user events, such as clicking a button or choosing an item from a drop-down list.

5. Call the `stop` method.

Like the `init` method, the default implementation of the `stop` method doesn't do anything, but you can override it to perform any processing necessary as the program terminates, such as closing database resources or saving files.

Launching the Application

As you know, the standard entry-point for Java programs is the `main` method. Here is the `main` method for the Click Me program:

```
public static void main(String[] args)
{
    launch(args);
}
```

As you can see, the `main` method consists of just one statement, a call to the `Application` class' `launch` method.

The `launch` method is what actually starts a JavaFX application. The `launch` method is a `static` method, so it can be called in the `static` context of the `main` method. It creates an instance of the `Application` class and then starts the JavaFX lifecycle, calling the `init` and `start` methods, waiting for the application to finish, and then calling the `stop` method.

The `launch` method doesn't return until the JavaFX application ends. Suppose you wrote the `main` method for the Click Me program like this:

```
public static void main(String[] args)
{
    System.out.println("Launching JavaFX");
    launch(args);
    System.out.println("Finished");
}
```

Then, you would see `Launching JavaFX` displayed in the console window while the JavaFX application window opens. When you close the JavaFX application window, you would then see `Finished` in the console window.

Overriding the start Method

Every JavaFX application must include a `start` method. You write the code that creates the user interface elements your program's user will interact with in the `start` method. For example, the `start` method in Listing 2-1 contains code that displays a button with the text `Click me please!`

When a JavaFX application is launched, the JavaFX framework calls the `start` method after the `Application` class has been initialized.

The start method for the Click Me program looks like this:

```
@Override public void start(Stage primaryStage)
{
    // Create the button
    btn = new Button();
    btn.setText("Click me please!");
    btn.setOnAction(e -> buttonClick());

    // Add the button to a layout pane
    BorderPane pane = new BorderPane();
    pane.setCenter(btn);

    // Add the layout pane to a scene
    Scene scene = new Scene(pane, 300, 250);

    // Finalize and show the stage
    primaryStage.setScene(scene);
    primaryStage.setTitle("The Click Me App");
    primaryStage.show();
}
```

To create the user interface for the Click Me program, the start method performs the following four basic steps:

1. Create a button control named `btn`, set its text to `Click me please!`, and specify that a method named `buttonClick` will be called when the user clicks the button.

For a more detailed explanation of this code, see the sections “Creating a Button” and “Handling an Action Event” later in this chapter.

2. Create a layout pane named `pane` and add the button to it.

For more details, see the section “Creating a Layout Pane” later in this chapter.

3. Create a scene named `scene` and add the layout pane to it.

For more details, see the “Making a Scene” section later in this chapter.

4. Finalize the stage by setting the scene, setting the stage title, and showing the stage.

See the “Setting the Stage” section later in this chapter for more details.

You find pertinent details of each of these blocks of code later in this chapter. But before I proceed, I want to point out a few additional salient details about the `start` method:

- ✓ The `start` method is defined as an abstract method in the `Application` class, so when you include a `start` method in a JavaFX program, you're actually overriding the abstract `start` method.

Although it isn't required, it's always a good idea to include the `@Override` annotation to explicitly state that you're overriding the `start` method. If you omit this annotation and then make a mistake in spelling the method named (for example, `Start` instead of `start`) or if you list the parameters incorrectly, Java thinks you're defining a new method instead of overriding the `start` method.

- ✓ Unlike the `main` method, the `start` method is not a static method. When you call the `launch` method from the static `main` method, the `launch` method creates an instance of your `Application` class and then calls the `start` method.
- ✓ The `start` method accepts one parameter: the `Stage` object on which the application's user interface will display. When the application calls your `start` method, the application passes the main stage — known as the *primary stage* — via the `primaryStage` parameter. Thus, you can use the `primaryStage` parameter later in the `start` method to refer to the application's stage.

Creating a Button

The button displayed by the Click Me program is created using a class named `Button`. This class is one of many classes that you can use to create user interface controls. The `Button` class and most of the other control classes are found in the package `javafx.scene.control`.

To create a button, simply define a variable of type `Button` and then call the `Button` constructor like this:

```
Button btn;  
btn = new Button();
```

In the code in Listing 2-1, the `btn` variable is declared as a class variable outside of the `start` method but the `Button` object is actually created within the `start` method. Controls are often declared as class variables so that you can access them from any method defined within the class. As you discover in the following section (“Handling an Action Event”), a separate method named `buttonClicked` is called when the user clicks the button. By defining the `btn` variable as a class variable, both the `start` method and the `buttonClicked` method have access to the button.

To set the text value displayed by the button, call the `setText` method, passing the text to be displayed as a string:

```
btn.setText("Click me please!");
```

Here are a few additional tidbits about buttons:

- ✓ The `Button` constructor allows you to pass the text to be displayed on the button as a parameter, as in this example:

```
Btn = new Button("Click me please!");
```

If you set the button's text in this way, you don't need to call the `setTitle` method.

- ✓ The `Button` class is one of many classes that are derived from a parent class known as `javafx.scene.control.Control`. Many other classes derive from this class, including `Label`, `TextField`, `ComboBox`, `CheckBox`, and `RadioButton`.
- ✓ The `Control` class is one of several different classes that are derived from higher-level parent class called `javafx.scene.Node`. `Node` is the base class of all user-interface elements that can be displayed in a scene. A control is a specific type of node, but there are other types of nodes. In other words, all controls are nodes, but not all nodes are controls. You can read more about several other types of nodes later in this book.

Handling an Action Event

When the user clicks a button, an *action event* is triggered. Your program can respond to the event by providing an *event handler*, which is simply a bit of code that will be executed whenever the event occurs. The Click Me program works by setting up an event handler for the button; the code for the event handler changes the text displayed on the button.

As you read in Chapter 3, there are several ways to handle events in JavaFX. For now, I look briefly at one of the simplest methods, which requires simply that you specify that a method be called whenever the event occurs and then provide the code to implement that method.

To specify the method to be called when the user clicks a button, you call the `setOnAction` method of the button class. Here's how it's done in Listing 2-1:

```
btn.setOnAction(e -> buttonClick());
```

If the syntax used here seems a little foreign, that's because it uses a new feature of Java 8 called *Lambda expressions*. As used in this example, there are three elements to this new syntax:

- ✓ The argument `e` represents an object of type `ActionEvent`, which the program can use to get detailed information about the event.
The Click Me program ignores this argument, so you can ignore it too, at least for now.
- ✓ The arrow operator (`->`) is a new operator introduced in Java 8 for use with Lambda expressions.
- ✓ The method call `buttonClick()` simply calls the method named `buttonClick`.

I discuss Lambda expressions in Chapter 3.

After `buttonClick` has been established as the method to call when the user clicks the button, the next step is to code the `buttonClick` method. You find it near the bottom of Listing 2-1:

```
public void buttonClick()
{
    if (btn.getText() == "Click me please!")
    {
        btn.setText("You clicked me!");
    }
    else
    {
        btn.setText("Click me please!");
    }
}
```

This method uses an `if` statement to alternately change the text displayed by the button to either `You clicked me!` or `Click me please!`. In other words, if the button's text is `Click me please!` when the user clicks the button, the `buttonClicked` method changes the text to `You clicked me!`. Otherwise, the `if` statement changes the button's text back to `Click me please!`.

The `buttonClicked` method uses two methods of the `Button` class to perform its work:

- ✓ **getText:** Returns the text displayed by the button as a string
- ✓ **setText:** Sets the text displayed by the button

For more information about handling events, see Chapter 3.

Creating a Layout Pane

By itself, a button is not very useful. You must actually display it on the screen for the user to be able to click it. And any realistic JavaFX program will have more than one control. The moment you add a second control to your user interface, you need a way to specify how the controls are positioned relative to one another. For example, if your application has two buttons, do you want them to be stacked vertically, one above the other, or side by side?

That's where layout panes come in. A *layout pane* is a container class to which you can add one or more user-interface elements. The layout pane then determines exactly how to display those elements relative to each other.

To use a layout pane, you first create an instance of the pane. Then, you add one or more controls to the pane. When you do so, you can specify the details of how the controls will be arranged when the pane is displayed. After you add all the controls to the pane and arrange them just so, you add the pane to the scene.

JavaFX provides a total of eight distinct types of layout panes, all defined by classes in the package `javafx.scene.layout`. The Click Me program uses a type of layout called a *border pane*, which arranges the contents of the pane into five general regions: top, left, right, bottom, and center. The `BorderPane` class is ideal for layouts in which you have elements such as a menu and toolbar at the top, a status bar at the bottom, optional task panes or toolbars on the left or right, and a main working area in the center of the screen.

The lines that create the border pane in the Click Me program are

```
BorderPane pane = new BorderPane();  
pane.setCenter(btn);
```

Here, a variable of type `BorderPane` is declared with the name `pane`, and the `BorderPane` constructor is called to create a new `BorderPane` object. Then, the `setCenter` method is used to display the button (`btn`) in the center region of the pane.

Here are a few other interesting details about layout panes:

- ✓ Layout panes automatically adjust the exact position of the elements they contain based on the size of the elements contained in the layout as well as on the size of the space in which the layout pane is displayed.
- ✓ I said earlier that controls are a type of node, and that you would read about other types of nodes later in this book. Well, you just read about one: A layout pane is also a type of node.

- ✓ Each region of a border pane can contain a node. Because a layout pane itself is a type of node, each region of a border pane can contain another layout pane. For example, suppose you want to display three controls in the center region of a border pane. To do that, you'd create a second layout pane and add the three controls to it. Then, you'd set the second layout pane as the node to be displayed in the center region of the first layout pane.
- ✓ You read more about the `BorderPane` class and a few other commonly used layout panes in Chapter 5. You also can read about the layout panes that aren't as commonly used in Chapter 13.

Making a Scene

After you create a layout pane that contains the controls you want to display, the next step is to create a scene that will display the layout pane. You can do that in a single line of code that declares a variable of type `Scene` and calls the `Scene` class constructor. Here's how I did it in the Click Me program:

```
Scene scene = new Scene(pane, 300, 250);
```

The `Scene` constructor accepts three arguments:

- ✓ A node object that represents the *root node* to be displayed by the scene.
A scene can have only one root node, so the root node is usually a layout pane, which in turn contains other controls to be displayed. In the Click Me program, the root node is the border layout pane that contains the button.
- ✓ The width of the scene in pixels.
- ✓ The height of the scene in pixels.

Note: If you omit the width and height, the scene will be sized automatically based on the size of the elements contained within the root node.

You can find out about some additional capabilities of the `Scene` class in Chapter 4.

Setting the Stage

If the *scene* represents the nodes (controls and layout panes) that are displayed by the application, the *stage* represents the window in which the scene is displayed. When the JavaFX framework calls your application's `start`

method, it passes you an instance of the `Stage` class that represents the application's primary stage — that is, the stage that represents the application's main window. This reference is passed via the `primaryStage` argument.

Having created your scene, you're now ready to finalize the primary stage so that the scene can be displayed. To do that, you must do at least two things:

- ✓ Call the `setScene` method of the primary stage to set the scene to be displayed.
- ✓ Call the `show` method of the primary stage to display the scene.

After you call the `show` method, your application's window becomes visible to the user and the user can then begin to interact with its controls.

It's also customary to set the title displayed in the application's title bar. You do that by calling the `setTitle` method of the primary stage. The last three lines of the `start` method for the Click Me application perform these functions:

```
primaryStage.setScene(scene);  
primaryStage.setTitle("The Click Me App");  
primaryStage.show();
```

When the last line calls the `show` method, the `Stage` displays — in other words, the window that was shown in Figure 2-1 displays onscreen.

You can read about additional capabilities of the `Stage` class in Chapter 4.

Examining the Click Counter Program

Now that I've explained the details of every line of the Click Me program, I look at a slightly enhanced version of the Click Me program called the Click Counter program. In the Click Me program that was shown in Listing 1-1 (in Chapter 1), the text displayed on the button changes when the user clicks the button. In the Click Counter program, an additional type of control called a *label* displays the number of times the user has clicked the button.

Figure 2-2 shows the Click Counter program in operation. The window at the top of this figure shows how the Click Counter program appears when you first start it. As you can see, the text label at the top of the window displays the text `You have not clicked the button`. The second window shows what the program looks like after you click the button the first time. Here, the label reads `You have clicked once`. When the button is clicked a second time, the label changes again, as shown in the third window. Here, the label reads `You have clicked 2 times`. After that, the number displayed by the label updates each time you click the button to indicate how many times the button has been clicked.

Figure 2-2:
The Click
Counter
program in
action.

Listing 2-2 shows the source code for the Click Counter program, and the following paragraphs describe the key points of how it works:

Listing 2-2: The Click Counter Program

```
import javafx.application.*;           →1
import javafx.stage.*;
import javafx.scene.*;
import javafx.scene.layout.*;
import javafx.scene.control.*;

public class ClickCounter extends Application   →7
{
    public static void main(String[] args)      →9
    {
        launch(args);                          →11
    }
}
```

```
Button btn; →14
Label lbl; →15
int iClickCount = 0; →16

@Override public void start(Stage primaryStage) →18
{
    // Create the button
    btn = new Button(); →21
    btn.setText("Click me please!"); →22
    btn.setOnAction(e -> buttonClick()); →23

    // Create the Label
    lbl = new Label(); →26
    lbl.setText("You have not clicked the button."); →27

    // Add the label and the button to a layout pane
    BorderPane pane = new BorderPane(); →30
    pane.setTop(lbl); →31
    pane.setCenter(btn); →32

    // Add the layout pane to a scene
    Scene scene = new Scene(pane, 250, 150); →35

    // Add the scene to the stage, set the title
    // and show the stage
    primaryStage.setScene(scene); →39
    primaryStage.setTitle("Click Counter"); →40
    primaryStage.show(); →41
}

public void buttonClick() →44
{
    iClickCount++; →46
    if (iClickCount == 1) →47
    {
        lbl.setText("You have clicked once."); →49
    }
    else
    {
        lbl.setText("You have clicked " →53
            + iClickCount + " times." );
    }
}
```

The following paragraphs explain the key points of the Click Me program:

- 1: The `import` statements reference the `javafx` packages that will be used by the Click Me program.
- 7: The `ClickMe` class extends `javafx.application.Application`, thus specifying that the `ClickMe` class is a JavaFX application.
- 9: As with any Java program, the `main` method is the main entry point for all JavaFX programs.
- 11: The `main` method calls the `launch` method, which is defined by the `Application` class. The `launch` method, in turn, creates an instance of the `ClickMe` class and then calls the `start` method.
- 14: A variable named `btn` of type `javafx.scene.control.Button` is declared as a class variable. Variables representing JavaFX controls are commonly defined as class variables so that they can be accessed by any method in the class.
- 15: A class variable named `lbl` of type `javafx.scene.control.Label` represents the `Label` control so that it can be accessed from any method in the class.
- 16: A class variable named `iClickCount` will be used to keep track of the number of times the user clicks the button.
- 18: The declaration of the `start` method uses the `@override` annotation, indicating that this method overrides the default `start` method provided by the `Application` class. The `start` method accepts a parameter named `primaryStage`, which represents the window in which the Click Me application will display its user interface.
- 21: The `start` method begins by creating a `Button` object and assigning it to a variable named `btn`.
- 22: The button's `setText` method is called to set the text displayed by the button to `Click me please!`.
- 23: The `setOnAction` is called to create an event handler for the button. Here, a Lambda expression is used to simply call the `buttonClick` method whenever the user clicks the button.
- 26: The constructor of the `Label` class is called to create a new label.
- 27: The label's `setText` method is called to set the initial text value of the label to `You have not clicked the button.`

- 30: A border pane object is created by calling the constructor of the `BorderPane` class, referencing the border pane via a variable named `pane`. The border pane will be used to control the layout of the controls displayed on the screen.
- 31: The border pane's `setTop` method is called to add the label to the top region of the border pane.
- 32: The border pane's `setCenter` method is called to add the button to the center region of the border pane.
- 35: A scene object is created by calling the constructor of the `Scene` class, passing the border pane created in line 30 to the constructor to establish the border pane as the root node of the scene. In addition, the dimensions of the scene are set to 300 pixels in width and 250 pixels in height.
- 39: The `setScene` method of the `primaryStage` is used to add the scene to the primary stage.
- 40: The `setTitle` method is used to set the text displayed in the primary stage's title bar.
- 41: The `show` method is called to display the primary stage. When this line is executed, the window that was shown in Figure 2-1 displays on the screen and the user can begin to interact with the program.
- 44: The `buttonClick` method is called whenever the user clicks the button.
- 46: The `iClickCount` variable is incremented to indicate that the user has clicked the button.
- 47: An `if` statement is used to determine whether the button has been clicked one or more times.
- 49: If the button has been clicked once, the label text is set to `You have clicked once`.
- 53: Otherwise, the label text is set to a string that indicates how many times the button has been clicked.

That's all there is to it. If you understand the details of how the Click Counter program works, you're ready to move on to Chapter 3. If you're still struggling with a few points, I suggest you spend some time reviewing this chapter and experimenting with the Click Counter program in TextPad, Eclipse, or NetBeans.

The following paragraphs help clarify some of the key sticking points that might be tripping you up about the Click Counter program and JavaFX in general:

- ✓ **When does the program switch from static to non-static?** Like every Java program, the main entry point of a JavaFX program is the static `main` method.

In most JavaFX programs, the static `main` method does just one thing: It calls the `launch` method to start the JavaFX portion of the program. The `launch` method creates an instance of the `ClickCounter` class and then calls the `start` method. At that point, the program is no longer running in a static context because an instance of the `ClickCounter` class has been created.

- ✓ **Where does the `primaryStage` variable come from?** The `primaryStage` variable is passed to the `start` method when the `launch` method calls the `start` method. Thus, the `start` method receives the `primaryStage` variable as a parameter.

That's why you won't find a separate variable declaration for the `primaryStage` variable.

- ✓ **How does the `->` operator work?** The `->` operator is used to create what is known as a Lambda expression. *Lambda expressions* are a new feature of Java 8 that are used in situations that would've previously required an anonymous class. Don't worry if you don't understand how the Lambda expression works. I explain them in detail in Chapter 3.
